The Nevada Coincident Employment Index measures the ups and downs of the Nevada economy, using an index of employment variables. The Nevada Leading Employment Index also measures the ups and downs of the Nevada economy, providing a signal about the future direction of the coincident index. The coincident index provides the benchmark series that defines the employment cycle or reference cycle in Nevada. The leading index then tracks the economy relative to that reference cycle. A good leading index will provide signals about the future path of the reference cycle.

Figures 1 and 2 depict the coincident and leading indexes with data through April 2020. Figure 1 shows that the coincident index plummeted to a level not seen since January 1994, more than a quarter of a century ago. The chart encompasses four recessions in employment, including the recent Great Recession. The peak of the last employment cycle for this recession in Nevada occurred in March 2007. The coincident index then regressed steadily to bottom out in October 2009. At the moment, we call the peak of the most recent expansion in February 2020.

Figure 2 shows the leading index diving to a level not seen in our sample period. The previous low in our sample occurred in April 1982. The chart shows the leading index and its movements relative to Nevada recessions in its employment cycle captured by the coincident index. For the most recent employment recession the leading index provided a clear signal by peaking in January 2006, fourteen months before the coincident index reached its peak, and bottoming out in May 2009, five months before the coincident index bottomed out. The March data saw downward movements in both the coincident and leading indexes. The April data drove both indexes downward by much larger increments.

The April release tells a consistent, negative story for the coincident index on a year-over-year and month-over-month basis. The unemployment rate (inverted), household employment, nonfarm employment, and the insured unemployment rate (inverted) all moved in a negative direction. For the leading index, housing permits, the short-duration unemployment rate (inverted), and commercial permits moved in a negative direction on
a month-over-month and year-over-year basis. Initial claims for unemployment insurance (inverted) moved in a positive direction only month-over-month, while construction employment and the real 10-year Treasury interest rate (inverted) moved in a positive direction on only a year-over-year basis.

Overall, the coincident and leading indexes fell on a year-over-year (month-over-month) basis by 56.6 (53.4) and 20.1 (17.8) percent, respectively. See Figures 1 and 2. This downturn (recession) differs from past recessions in that the government imposed lockdown caused the recession and not some imbalance in the economy. As a result, the leading index did not provide a warning that preceded the recession.

Developed by Stephen M. Miller (director of CBER and professor of economics, 702-895-3969) and Mustafa Gunaydin (former graduate student in economics). DETR provided a grant to support Mr. Gunaydin’s research during the development of the indexes.

2 All series are initially not seasonally adjusted and then seasonally adjusted using Census X12. In some instances, our seasonally adjusted series differ from the seasonally adjusted data reported by the Bureau of Labor Statistics. The Nevada Coincident Employment Index includes four employment measures – household employment, nonfarm employment, the unemployment rate (inverted, since an upward movement in the jobless rate is a “negative”), and the insured unemployment rate (inverted). The Nevada Leading Employment Index includes six employment related measures – initial claims for unemployment insurance (inverted), the real 10-year Treasury rate (inverted), housing permits, commercial permits, construction employment, and the short-duration unemployment rate (inverted). While not employment variables, housing and commercial permits, as well as the real 10-year Treasury rate, closely relate to construction activity and construction employment. All data are seasonally adjusted and come from DETR, CBER, and the Federal Reserve Bank of St. Louis FRED® data. The description of the construction method is posted at http://cber.unlv.edu/nvindices.pdf. Data availability restricts our coverage in the two indexes to monthly series beginning in January 1976. The data series for household employment, nonfarm employment, the unemployment rate, initial claims, and the real 10-year Treasury rate all begin in January 1976. Housing permits and the insured unemployment rate begin in January 1980 and March 1987, respectively. Commercial permits, construction employment, and the short-duration unemployment rate begin in January 1988, January 1990, and January 2001, respectively. Thus, the coincident index uses three series through March 1987, when we add the insured unemployment rate. The leading index begins with two series and adds housing permits in January 1980, commercial permits in January 1988, construction employment in January 1990, and finally, the short-duration unemployment rate in January 2001.
